

The Globe — Latitudes, Longitudes & Motions of the Earth

Subject: Physical Geography | NCERT Class 6 Ch. 2 & 3 | UPSC & State PSC Core

30-Second Snapshot

- Parallels of **latitude** run horizontally and decrease in size poleward, dividing the Earth into **Torrid, Temperate, and Frigid** heat zones based on solar incidence angles.
- Meridians of **longitude** are equal-length semi-circles converging at the poles; distances between them peak at the Equator and shrink to zero at the poles.
- The Earth rotates **360 degrees in 24 hours** (15 degrees per hour or 1 degree every 4 minutes); places east of Greenwich lead in time, while places west lag behind.
- Indian Standard Time (IST)** is calibrated along **82.5 degrees East** longitude, placing it exactly **5 hours 30 minutes ahead** of Greenwich Mean Time.
- Rotation** on an axis tilted at 23.5 degrees creates day and night separated by the **Circle of Illumination**, which does not coincide with the rotational axis.
- Revolution** along an elliptical orbit combined with the fixed axial tilt produces the seasons, marked by the **Summer Solstice (June 21)**, **Winter Solstice (December 22)**, and **Equinoxes (March 21 & September 23)**.

Parallels vs. Meridians: Coordinate Architecture

Structural Feature	Parallels of Latitude	Meridians of Longitude	Analytical & Navigational Impact
Geometric Form	Complete parallel circles oriented east-west	Equal-length semi-circles running north-south	Latitudes measure angular distance north/south; longitudes measure east/west.
Dimensional Variation	Size shrinks poleward; largest at Equator (0°), zero at poles (90°)	All meridians share identical lengths from pole to pole	Longitudes converge at the poles; inter-meridian distance peaks at the Equator (~111 km).
Primary Reference Line	Equator (0° latitude), dividing Northern and Southern Hemispheres	Prime Meridian (0° longitude, Greenwich), dividing Eastern and Western Hemispheres	Both reference baselines form the foundation for global grid coordinate positioning.
Primary Physical Function	Delineates planetary thermal insolation zones	Establishes local solar time and worldwide standard time zones	Combining latitude and longitude creates an orthogonal grid to pinpoint any terrestrial location.

Planetary Heat Zones & Time Kinematics

- The Three Latitudinal Heat Zones:**
 - Torrid Zone (23.5° N to 23.5° S):** The midday sun reaches the vertical zenith at least once a year on every parallel; receives maximum solar insolation.
 - Temperate Zones (23.5° to 66.5° N & S):** The midday sun never reaches the vertical zenith; incoming solar radiation arrives at slanting angles, yielding moderate seasonal temperatures.
 - Frigid Zones (66.5° to 90° N & S):** The sun remains low on the horizon with extreme slanting rays; causes perpetual cold and extended periods of darkness or daylight.
- Mathematical Time Computations:**
 - Full axial rotation = 360 degrees in 24 hours.
 - Hourly rate = 15 degrees per hour (360 divided by 24).
 - Degree rate = 1 degree every 4 minutes (60 divided by 15).
 - Directional Rule:** Eastward positions gain time (+), while westward positions lose time (-).
 - Indian Standard Time Calculation:** 82.5 degrees multiplied by 4 minutes = 330 minutes = +5 hours 30 minutes ahead of GMT.
- Axial Tilts and Diurnal Boundaries:**
 - Rotational axis tilt = 23.5 degrees from the vertical (66.5 degrees relative to the orbital plane).
 - Circle of Illumination:** The dynamic circular line dividing daylight from darkness across the globe.
 - Because of the 23.5-degree axial tilt, the Circle of Illumination cuts across latitude parallels rather than coinciding with the geographic rotational axis.

⚠ Common UPSC Exam Traps

- **Trap 1 (Meridian Length vs. Parallel Circumference):** Parallels of latitude are not equal in circumference; they shrink progressively toward the poles. Meridians of longitude, however, are all identical in length and converge at both poles.
- **Trap 2 (Circle of Illumination vs. Rotational Axis):** The Circle of Illumination does not align with the Earth's rotational axis. The axis is tilted 23.5 degrees from the vertical, while the illumination plane is always perpendicular to incoming solar rays.
- **Trap 3 (Directional Longitude Time Shifts):** Moving east of the Prime Meridian adds time (ahead of GMT), whereas moving west subtracts time (behind GMT). For example, at 15 degrees East it is 1:00 PM when it is 12:00 noon at Greenwich.
- **Trap 4 (Equinox Solar Alignments):** Equal day and night across the globe occur exclusively on the equinoxes (March 21 and September 23), when the midday sun is directly overhead at the Equator, not during solstices.

🎯 High-Yield Facts Box

Parameter / Concept	Exact Geographic Benchmark	Operational & Climatic Relevance
Indian Standard Meridian	82 degrees 30 minutes East	National timekeeping meridian passing through Mirzapur, Uttar Pradesh.
IST Time Offset	+5 hours 30 minutes ahead of GMT	Synchronizes rail, communication, and administrative networks across India.
Summer Solstice Date	June 21	Midday sun directly overhead at Tropic of Cancer; longest day in Northern Hemisphere.
Winter Solstice Date	December 22	Midday sun directly overhead at Tropic of Capricorn; longest day in Southern Hemisphere.
Equinox Dates	March 21 and September 23	Midday sun directly overhead at Equator; equal 12-hour day and night worldwide.

📝 Prelims Practice Challenge

Q1. Consider the following statements regarding parallels of latitude and meridians of longitude:

1. The linear distance between two successive parallels of latitude decreases progressively from the Equator toward the poles.
2. All meridians of longitude are of equal length and converge at the geographic poles.
3. Indian Standard Time is calculated based on the local solar time of the 82.5 degrees East meridian, which is five hours ahead of Greenwich Mean Time.

Which of the statements given above is/are correct?

- (A) 1 and 2 only
- (B) 2 only
- (C) 2 and 3 only
- (D) 1, 2, and 3

Answer: (B) 2 only

Explanation: Statement 1 is incorrect because the distance between parallels of latitude remains roughly constant (about 111 km), even though the size of the circles shrinks. Statement 2 is correct because all meridians are equal semi-circles that meet at the poles. Statement 3 is incorrect because Indian Standard Time is 5 hours and 30 minutes ahead of GMT, not 5 hours.

Q2. Consider the following statements regarding the motions of the Earth:

1. The Circle of Illumination coincides with the Earth's rotational axis during the summer and winter solstices.
2. The variation in the length of day and night across seasons is caused by the revolution of the Earth on an inclined axis.
3. During the equinoxes, the midday sun is vertically overhead at the Tropic of Cancer.

Which of the statements given above is/are correct?

- (A) 1 and 3 only
- (B) 2 only
- (C) 2 and 3 only
- (D) 1, 2, and 3

Answer: (B) 2 only

Explanation: Statement 1 is incorrect because the Circle of Illumination never coincides with the tilted rotational axis, aligning only perpendicular to solar rays. Statement 2 is correct because seasons and varying day lengths result from orbital revolution combined with the fixed 23.5-degree axial tilt. Statement 3 is incorrect because the midday sun is vertically overhead at the Equator during the equinoxes, not the Tropic of

 Mains Practice Question (10 Marks / 150 Words)

Question: "Explain how the tilt of the Earth's axis and its orbital revolution interact to produce seasonal variations and unequal day lengths across different latitudes."

 Structured Answer Framework:**• Introduction (25–30 words):**

Define the Earth's two primary motions: axial rotation (causing diurnal cycles) and orbital revolution (365.25 days). Note that the rotational axis maintains a constant 23.5-degree tilt relative to the perpendicular of its orbital plane.

• Body Arguments (80–90 words):

- *Seasonal Variation:* As the Earth revolves, this fixed tilt causes each hemisphere to alternate leaning toward and away from the Sun. At the Summer Solstice (June 21), the Northern Hemisphere tilts toward the Sun, receiving direct solar rays at the Tropic of Cancer (23.5° N) to produce northern summer. At the Winter Solstice (December 22), the Southern Hemisphere tilts toward the Sun, creating southern summer.
- *Unequal Day Lengths:* The Circle of Illumination bisects the globe perpendicular to incoming solar rays. Because the axis is tilted, the illumination circle cuts across latitude parallels unequally. The hemisphere tilted toward the Sun has more than half of its latitudinal circles illuminated, resulting in longer days and shorter nights.
- *Polar Extremes:* Latitudes beyond the polar circles (66.5° N and S) remain entirely on one side of the illumination circle for months, producing up to six months of continuous daylight or darkness.

• Conclusion / Way Forward (25–30 words):

The interaction of axial tilt and revolution establishes global seasonal transitions and latitudinal temperature differences, driving global wind systems and ocean currents.
