

Subject: Physical Geography & Geomorphology | NCERT Class 7 Ch. 2-3 & Class 11 Ch. 2-3 | UPSC & State PSC Core

< 30-Second Snapshot

- The universe expanded from a singularity **13.7 billion years ago** (Big Bang); Earth differentiated into density-stratified layers as heavy **iron and nickel sank to the core**.
- Earth's primordial atmosphere formed via **degassing**, while cooling condensation formed oceans **4,000 million years ago**, followed by photosynthetic oxygenation.
- Earth's interior is mapped indirectly via seismic waves: **P-waves** travel through all states of matter, while **S-waves travel only through solids**.
- The **S-wave shadow zone (beyond 105 degrees)** proves the **outer core is liquid**, whereas high pressure keeps the inner core solid.
- The **Lithosphere (10–200 km)** floats upon the ductile, semi-molten **Asthenosphere (up to 400 km)**, which supplies magma for volcanism.
- Rocks cycle through three classes: **Igneous** (basalt, granite), **Sedimentary** (fossiliferous sandstone), and **Metamorphic** (slate, marble).
- Plutonic intrusions cool within the crust to form distinct structures: massive **batholiths**, dome-shaped **laccoliths**, saucer-shaped **lopoliths**, horizontal **sills**, and vertical **dykes**.

🏠 Stratigraphic Architecture of the Earth

Earth Layer	Depth / Boundary	Compositional Material	Mechanical State & Physical Behavior
Continental Crust	0 to 30 km (up to 70 km under mountains)	Silica and Alumina (Sial); granitic rock	Brittle solid; lowest density among solid layers.
Oceanic Crust	5 km average thickness	Silica and Magnesium (Sima); basaltic rock	Dense, thin, brittle solid; forms oceanic floors.
Asthenosphere	Upper mantle down to 400 km	Peridotite and ultramafic silicates	Semi-molten, plastic, ductile; main magma source.
Lower Mantle	400 km to 2,900 km (Base at D" layer)	Dense silicate minerals	High-pressure rigid solid; convects over geological time.
Outer Core	2,900 km to 5,150 km (Gutenberg boundary)	Nickel and Iron (Nife) alloy	Liquid state; blocks S-waves; generates geomagnetic field.
Inner Core	5,150 km to 6,378 km (Lehmann boundary)	Metallic Nickel and Iron (Nife)	Solid metallic sphere under extreme lithostatic pressure.

📐 Seismic Wave Kinematics & Volcanic Morphologies

- **Seismic Wave Dynamics & Shadow Zones:**
 - **P-waves (Primary):** Compressional/longitudinal waves; particle motion parallel to path; fastest velocity; travel through solids, liquids, and gases.
 - **S-waves (Secondary):** Transverse/shear waves; particle motion perpendicular to path; intermediate velocity; propagate strictly through solid rock.
 - **Surface Waves (L-waves):** Travel along the crustal interface; slowest velocity; generate high-amplitude displacement and cause the greatest structural damage.
 - **Shadow Zone Geometry:**
 - P-wave shadow zone: Annular ring from 105° to 145° from the epicenter, caused by refraction at the mantle-core boundary.
 - S-wave shadow zone: Spans the entire region from 105° to 180° (over 40% of the Earth's surface) because S-waves cannot enter the liquid outer core.
- **Volcanic Classification & Intrusive Plutons:**
 - **Shield Volcanoes:** Effusive, low-viscosity basalt lava with gentle slopes (e.g.,

Hawaiian volcanoes).

- **Composite Volcanoes:** Explosive eruptions of viscous andesitic lava alternating with pyroclastic ash beds.
- **Calderas:** Massive, highly explosive depressions formed by summit collapse into an evacuated magma chamber.
- **Flood Basalts:** Enormous continental fissure outpourings of fluid lava (e.g., the Deccan Traps).
- **Intrusive Plutonic Structures:**
 - **Batholith:** Large, deep granitic intrusion forming mountain cores.
 - **Laccolith:** Dome-shaped intrusion with a flat base, fed by a vertical pipe conduit.
 - **Lopolith & Phacolith:** Saucer-shaped basin intrusion (lopolith); lens-shaped intrusion in folded folds (phacolith).
 - **Sill & Dyke:** Concordant horizontal layer (sill); discordant vertical wall-like sheet (dyke).

⚠ Common UPSC Exam Traps

- **Trap 1 (S-wave Shadow Zone Extent):** The S-wave shadow zone is not smaller than the P-wave shadow zone. The P-wave shadow zone is an annular band between 105° and 145°, whereas the S-wave shadow zone covers everything beyond 105°, spanning over 40% of the Earth's surface.
- **Trap 2 (Asthenosphere vs. Lithosphere):** The lithosphere is not just the crust; it consists of the entire crust plus the uppermost rigid mantle (10 to 200 km thick). The asthenosphere lies immediately beneath it (down to 400 km) and is ductile and plastic.
- **Trap 3 (Planetary Light Years):** A light year is a measure of astronomical distance (approx. 9.46×10^{12} km), not an interval of time.
- **Trap 4 (Sills vs. Dykes):** Sills are horizontal, concordant igneous bodies that run parallel to existing sedimentary strata. Dykes are vertical or steeply inclined discordant sheets that cut across bedding planes.

🎯 High-Yield Facts Box

Scientific Metric / Feature	Benchmark Value	Geomorphological Significance
Age of the Universe	13.7 billion years	Big Bang singularity expansion timeline.
Deepest Drill Hole	12 km (Kola Peninsula, Arctic Russia)	Deepest direct physical sampling of the continental crust.
Core-Mantle Boundary	2,900 km depth	Gutenberg Discontinuity; marks the boundary where S-waves terminate.
Deccan Traps Origin	Flood basalt fissure volcanism	Formed expansive volcanic plateau layers across western India.
Earthquake Energy Metric	Richter Scale (0 to 10, Logarithmic)	Quantifies absolute seismic energy release at the focus.

📝 Prelims Practice Challenge

Q1. With reference to earthquake waves and Earth's interior, consider the following statements:

1. P-waves vibrate parallel to the direction of wave propagation, whereas S-waves vibrate perpendicular to the wave direction.
2. The shadow zone of P-waves covers a significantly larger portion of the Earth's surface than the shadow zone of S-waves.
3. The inability of S-waves to penetrate beyond 105 degrees from an earthquake epicenter provides conclusive evidence of a liquid outer core.

Which of the statements given above are correct?

- (A) 1 and 2 only

- (B) 1 and 3 only
- (C) 2 and 3 only
- (D) 1, 2, and 3

Answer: (B) 1 and 3 only

Explanation: Statement 1 is correct because P-waves are longitudinal (parallel compression) and S-waves are transverse (perpendicular shear). Statement 2 is incorrect because the S-wave shadow zone extends continuously from 105° to 180° (over 40% of Earth), making it far larger than the P-wave shadow zone (105° to 145°). Statement 3 is correct because S-waves cannot travel through liquids, confirming that the outer core is molten.

Q2. Consider the following pairs of intrusive volcanic landforms and their structural forms:

1. **Laccolith** — Saucer-shaped intrusive body with a concave-downward profile
2. **Phacolith** — Lens-shaped mass found at the crest of anticlines or trough of synclines
3. **Dyke** — Near-vertical, wall-like discordant igneous intrusion cutting across rock beds

Which of the pairs given above is/are correctly matched?

- (A) 1 and 2 only
- (B) 2 and 3 only
- (C) 3 only
- (D) 1, 2, and 3

Answer: (B) 2 and 3 only

Explanation: Pair 1 is incorrectly matched because a laccolith is a dome-shaped intrusion with a flat horizontal base; a saucer-shaped concave intrusion is a lopolith. Pairs 2 and 3 are correctly matched: phacoliths lodge in folded crests/troughs, and dykes are discordant vertical wall-like sheets.

Mains Practice Question (10 Marks / 150 Words)

Question: "Discuss how seismic wave shadow zones serve as an indispensable indirect tool for deciphering the internal compositional boundaries and physical states of the Earth."

Structured Answer Framework:

• **Introduction (25–30 words):**

Direct observation of Earth's interior is limited to shallow depths (Kola borehole reaches 12 km). Scientists therefore rely on seismic body waves (P-waves and S-waves) generated during earthquakes to probe internal layers down to the core (6,378 km).

• **Body Arguments (80–90 words):**

- **Wave Properties:** P-waves are compressional waves that pass through solids, liquids, and gases. S-waves are shear waves that propagate strictly through solid media. Wave velocity increases with density, causing paths to bend and refract at internal boundaries.
- **S-Wave Shadow Zone (Beyond 105°):** The complete absence of direct S-waves beyond 105° from an epicenter (covering over 40% of the globe) proves that the outer core (2,900 km to 5,150 km) is liquid, as it blocks shear wave transmission.
- **P-Wave Shadow Zone (105° to 145°):** P-waves refract sharply downward at the 2,900 km core-mantle boundary due to a drop in velocity, leaving an annular shadow zone between 105° and 145°. P-waves re-emerge beyond 145°, and their velocity spikes at 5,150 km, confirming a solid inner core under extreme lithostatic pressure.

• **Conclusion / Way Forward (25–30 words):**

Mapping shadow zones and wave refractions provides the foundational blueprint for Earth's mechanical layers: the brittle crust, ductile asthenosphere, solid lower mantle, liquid outer core, and solid inner core.
